

Do you think we will live to see the singularity and gain digital immortality?

We think we are already on the cusp of it.

Distributed blockchain and IPFS are the best fit for this, and we'll show you how.

In the era of the rapid development of artificial intelligence, blockchain and data storage systems, it is possible to assume that AI will soon appear, which will be able to completely recreate a person's personality in the form of a digital avatar along his digital footprint.

A very rough example is how Google photographs the earth from satellites, and then uses algorithms to build three-dimensional maps of cities.

Given that almost the entire world has already been photographed, filmed on video (with almost exact geolocation), the creation of a complete virtual model of our world is just a matter of time.

Yes, it's all about the metaverse.

Digital rebirth, digital immortality, singularity, consciousness transfer.

Why does humanity need it?

Two aspects that stop the further movement of human evolution -
it is a physical shell and time.

Just to fly out of the solar system, Voyager 1 took more than 45 years, which is more than half of the average human life.

Imagine the crew of an intergalactic ship that consists of digital personalities and for life support that needs only electricity.

And if something happens to the ship, there is always a backup copy on one of the planets of the solar system.

Large corporations have been collecting the human digital footprint for a long time, not for the benefit of humanity, but in order to capitalize on it, creating more and more consumption. And in connection with this, wars and crises appear that throw some countries literally into the Middle Ages.

Two development paths:

1. Digital cryochamber.

We can assume that in order to create a legitimate digital footprint for recreating a person, we will need media files about a person, and the more the better.

It can be just a photo, maybe a video, or maybe a 3D scan of the whole person.

And something else is needed that can understand the nature of a person in the future, so in the future we will develop our own chatbot, after communicating with which the necessary data will be collected for storage.

In order to limit the access of third parties to this information during all this time, we will develop a smart contract that will first store your data anonymized, dissolving it in IPFS and blockchain. And after, for example, 30 years, the address will begin to create a transaction in the blockchain with the message #resurrectme and the AI of the future, seeing this transaction, will launch an algorithm for creating a digital identity and moving it to a digitized copy of our world.

Perhaps it will be possible to move to an irl shell that can be rented, these are the details.

2. Digital graveyard.

This is a public option for storing your (or someone else's) digital footprint. For example, if you want to prepare for death in advance and leave a will, or immortalize an already deceased person.

The technical connection is exactly the same as with the cryochamber, and will make it easier to survive the loss, as well as descendants can communicate with your digital copy in 100 years and learn more about themselves.

Plus, you can create a digital will, for example "if there are no transactions on my address for more than a year, then send all my savings to my relatives at: address1, address2, address3".

Ethical side

How will this be perceived by believers of different faiths and skeptics?

There are no contradictions in this project either from a philosophical or esoteric or religious point of view.

Most of the teachings in one way or another are either preparing a person for death or trying to reach the absolute, and this should be a very good way to do this.
